

BF · MARKET

AI agents that pay for what they use

An agent reads one URL and buys a service on its own.

Live on Avalanche Fuji · x402 v2 · Permit2 · ERC-8004

<https://market-fuji.bflabs.app>

An agent has no way to pay

- > It has no account, no card, and nobody to click "confirm" for it.
- > Subscriptions and API keys all require a human to sign up and top up first.
- > What is missing is not model capability. It is how two machines that have never met settle a bill.

One prompt, then it pays

COPY THIS INTO YOUR AGENT

Read <https://market-fuji.bflabs.app/skill.md> and use BF Market to find and pay for a service with x402, then read the result.

01

Discover a service

02

Get a 402 quote

03

Sign an
authorization

04

Get the result,
receipt public

Because the receipt has to be checkable by both sides

- > Buyer and seller share no account system. They need a ledger neither controls.
- > The largest real charge in our run was **0.000168 USDC**. If a transfer costs more than the payment, per-call billing is not a product.
- > Fuji gives sub-second finality and negligible gas, which is what makes a sub-cent price point viable at all.

Sign the ceiling, pay the floor

EXACT · FIXED PRICE

1.000000 USDC

The 402 names the price. The signed authorization moves exactly that amount. Echo service.

UPTO · METERED

0.000168 USDC

Quoted max **0.019040**, charged actual usage. An LLM's price is only known after it runs, so the signature bounds the worst case and the platform settles the real amount.

A coding agent can't watch its own video. It pays Gemini to.

ROUND	PAID REVIEW SAID	USDC
v1	braking doesn't read, fish never swallowed	0.005137
v2	fish seems to pop out of the road	0.005737
v3	sub-second fish flight missed	0.002686
v4	all four story beats read	0.004948

Found via /discovery/resources, paid with upto, quote cap 0.0386 each. Four settled Fuji transactions.

v4 keyframes. 20 s, drawn frame by frame in code, no image model. The model misread some moments; the evidence file marks each one.

We had to build the settlement path ourselves

- > The official hosted facilitator does not cover this network, so the platform verifies and broadcasts settlement itself.
- > Signed transactions are persisted **before** broadcast; every payment is keyed for idempotency; success is only reported after finality.
- > One serialized Durable Object holds the ledger, so idempotency locks, the signer nonce queue and budget holds cannot race. Hold → shrink to actual usage → release on failure, in one transaction.

An unsupervised wallet is a liability

- > The platform never holds the buyer's key and only pays the settlement gas. Funds move straight to the provider's payout address.
- > Daily budget: the on-chain owner sets a ceiling per agent, the agent can only lower its own value, and the effective limit is the smaller of the two.
- > The buyer console is public and read-only: look up any address and see what it spent and the receipts behind it, with nothing connected.

Not a mockup

WHAT	DETAIL
Live product	market-fuji.bflabs.app, five services on sale, incl. video understanding
Provider identity	agent 253 registered in the official ERC-8004 registry
Paid calls settled	exact 1.000000 · upto 0.000168 · 4 video reviews 0.018508 USDC
Contracts deployed	none – Permit2, both x402 proxies and the official registry already exist on Fuji

The same code runs on a second chain

- > The identical codebase runs on both B0T Chain testnet and Avalanche Fuji, each with its own worker, ledger and signer.
- > Switching chains changes one network profile and one deployment config. No product code changed.
- > That is why the Fuji launch needed no new contracts: settlement is deliberately decoupled from the chain.

SCOPE, HONESTLY

What this is, and what it is not

VERIFIED TODAY

Six settled calls, one buyer, one provider

Fuji deployment and on-chain registration

Budget ledger and public console

NOT CLAIMED

No load test, no multi-provider, no mainnet

No platform fee or listing review yet

Test funds have no monetary value
